C Language Programming

Why C?

Why C?

ANSI C

The Embedded
Difference

Examples

- **The language suitable for embedded systems**
 - Microcontrollers accept instructions in machine code
 - All software: assembly, C, C++, Java must be translated into machine code in order to be executed by the CPU
 - Interpretation of machine code by the engineer is error prone and time consuming
 - Efficiency of the programming language: embedded processors have limited processor power and limited available memory

Why C?

Why C?

ANSI C

The Embedded
Difference

Examples

- **The language suitable for embedded systems**
- Compromise between safety, maintainability, portability
- Characteristics of the required language:
 - efficient
 - high-level
 - offers low-level access to hardware
 - well defined
 - in common use
 - read from and write to particular memory locations (e.g. by a mechanism such as “pointers”)
 - reuse the code (**which has already been tested**)

C is a solution

Why C?

Why C?

ANSI C

The Embedded
Difference

Examples

- **Features of the C programming language:**
 - “mid-level”
 - “low-level” features (access to hardware via pointers)
 - “high-level” features (support for functions and modules)
 - In common use
 - Different compilers are available for every embedded processor (8-bit to 32-bit or more)

ANSI C – Identifiers

□ C Program

Why C?

ANSI C

Identifiers

Numbers, Variables

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

Main file

Data declarations

Main

**Declarations
Instructions
Blocks**

Sub program

**Declarations
Instructions
Blocks**

**Used data
Called subroutines**

ANSI C – Identifiers

Why C?

ANSI C

Identifiers

Numbers, Variables

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Tokens:**

- identifiers
- keywords
- constants
- string literals
- operators
- other separators
- blanks, horizontal and vertical tabs, new lines and comments (“white spaces”) - ignored

ANSI C – Identifiers

Why C?

ANSI C

Identifiers

Numbers, Variables

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- **Identifiers:**
 - a sequence of letters and digits
 - functions, structures, unions and enumeration members of structures or unions, enumeration constants, defined types (typedef)
- **Rules:**
 - The first character must be a letter
 - The underscore counts as a letter
 - Upper and lower case letter are different
 - Identifiers may have any length and for internal identifiers, at least the first 31 characters are significant

ANSI C – Identifiers

Why C?

ANSI C

Identifiers

Numbers, Variables

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- The compiler allocates memory for all identifiers
- As the compiler reads a program, it records all identifier names in a symbol table.
- The compiler uses the symbol table internally as a reference to keep track of the identifiers: name, type and the location in memory
- When the compiler finishes translating a program into machine language, it will have replaced all the identifier names used in the program with instructions that refer to the memory addresses associated with these identifiers

ANSI C – Identifiers

Why C? □ An identifier can not be a C Keywords:

ANSI C	auto	double	int	struct
Identifiers	break	else	long	switch
Numbers, Variables	case	enum	register	typedef
Expressions	char	extern	return	union
Program flow	const	float	short	unsigned
Arrays & Pointers	continue	for	signed	void
Functions	default	goto	sizeof	volatile
Preprocessor	do	if	static	while
The Embedded Difference				
Examples				

□ Some implementations also reserve the **asm** keyword

ANSI C – Identifiers

Why C?

ANSI C

Identifiers

Numbers, Variables

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Variable Data Identifiers:

- Identifiers which represent variable data values, called **variables**, require portions of memory which can be altered during the execution of the program
- The compiler will allocate a block of its data memory space, usually in RAM, for each variable identifier
 - **Example: variable declaration**
int currentTemperature; / will cause the compiler to allocate 2 or 4 bytes of RAM */*
- The keyword **int** in the variable declaration tells the compiler that *currentTemperature* will contain an integer value and will require 2 or 4 bytes of RAM to contain this value

ANSI C – Identifiers

• Constant Data Identifiers:

- allocated from computer program memory space
- constant data values do not require alterable memory: once the value of a constant has been written in memory it need never change => the compiler will allocate a block of its program memory space, usually in ROM, for each of these identifiers (most of the cases)
 - **Example: constant data value declaration**
const int maxTemperature = 20;
- the keyword **const** tells the compiler that the identifier is a constant and that 2 or 4 bytes in ROM should be reserved to contain the value 20
- when the identifier *maxTemperature* is used in the program it refers to the memory location in ROM which contains the value 20.

Why C?

ANSI C

Identifiers

Numbers, Variables

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

ANSI C – Identifiers

Why C?

ANSI C

Identifiers

Numbers, Variables

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Function Identifiers:

- not altered during program execution
- Once the value of a function has been written in the computer's memory it need never change
- When a function is defined, the compiler places the program instructions associated with the function into ROM
- **What happens to the local variables used in a function's body of statements?**
- The compiler will write in the data memory, addresses where local variable values will be stored in RAM when the program runs
- Each program has a *main()* function

ANSI C – Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- Numbers
- Variables
- Memory class modifier
- External variables
- Scope rules
- Static variables
- Register variables
- Initialization

- Data Types
- Data encapsulation with *struct*
- Data encapsulation with *union*
- Bit fields
- Enumerated data types
- Definition of private types
- Type Conversion

ANSI C – Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- **Constants**
 - Text constants
 - Numerical constants
- **Text constants**
 - **char** Ex: 'P', 'R', '7', '#'
 - **string** Ex: "Politehnica"
- For **string constants** an array of appropriate length is reserved and the character '\0' is **automatically added to the end**. In this way the string end can be recognized by the program.

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- **Text constants**
- **Example: String Constant**

'S'	'y'	's'	't'	'e'	'm'	's'	'\0'
53	79	73	74	65	6D	73	00

A char constant doesn't end with the terminal '\0'

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- **Numerical constants**
 - Numbers always start with a digit
 - Expressing values in different notations except the decimal:
 - **0x**nnnn hexadecimal number (digits: 0-9, a-f or A-F)
 - **0**nnn octal number (digits: 0-7)
 - **0b**nnnn binary number (digits: 0,1)
 - **Example:**

```
// all octal values begin with 0
int octalInt = 030;

// all hex values begin with 0x
int hexadecimalInt = 0x40;

// all binary values begin with 0b
int binaryInt = 0b00100000;
```

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- **Numerical constants**
 - Long integer constants are specified with an ending **L**
 - **Example:** long var1 = 11L;
 - Unsigned integer constants are specified with an ending **U**
 - **Example:** unsigned int var2 = 5u;
 - Floating point values should contain a decimal point,
 - **Example:** float var3 = 2.;
 - Floating point values may be written with mantissa and exponent,
 - **Example:** float var4 = 0.4e-5;
- The suffixes may be omitted, but this might sometimes result to an error

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Symbolic definition of Constants**

- Symbolic constants are defined with the pre-processor directive **#define**

■ **Example:**

```
#define MAX 350
```

```
#define TEXT "Embedded Systems"
```

- **It is recommended to define a symbolic constant for each constant value for improved readability**

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Symbolic definition (**#define**) vs. **const**

- constants declared with **const** are stored in ROM - **disadvantage**
- constants declared with **const** are visible in debuggers - **advantage**
- symbolic constants do not take up space in ROM, but are not visible in debuggers;
- Symbolic constants are recommended for embedded systems where ROM memory is critical

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Variables** - characterized by:

- value
- address
- attribute (modifier)
- type
- Lifetime

[class] [modifier] [type] <name> [, <name1>][,...]

- When the compiler comes across a variable declaration it checks that the variable has not previously been declared and then allocates an appropriately sized block of RAM

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Variables

- The modifier can be one of:
 - **volatile**
 - **Const**
- **Volatile**
 - volatile <type> <name>
 - directs the compiler not to perform certain optimizations on an object because that object can have its value altered in ways beyond the control of the compiler
 - must always be read from its original location and is not kept in a register at any time
 - compiler optimizations are not available, therefore it must be used only if necessary
 - useful for controlling **access to memory-mapped device registers**, as well as for providing **reliable access to memory locations** used by asynchronous processes

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Const

- `const <type> <name>`
- allows only read access to the variable
- may only be initialized once in a program, the initialization being performed in the startup code
- allows the compiler to perform type checking
- **announces objects that may be placed in read-only memory**, and perhaps to increase opportunities for optimization

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Memory class modifiers

memory_class	local object	global object
<code>auto</code>	The object shall be located on the stack. As this is default the <code>auto</code> modifier may be omitted.	Meaningless.
<code>register</code>	The object shall be located in a register, if possible.	Meaningless.
<code>extern</code>	Impossible.	The object is declared and used in the current module but defined in a different one.
<code>static</code>	The object shall be located in memory but not on the stack.	The object shall not be public and only accessible in the current module.

■ **auto**

- default storage class
- local lifetime
- is not initialized automatically, but explicitly
- visible only in the block in which it is declared

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

❑ Memory class modifiers

- ❑ **static**
 - ❑ global lifetime
 - ❑ visible only within the block in which it is declared
- ❑ **register**
 - ❑ mostly obsolete
 - ❑ used for optimizations for heavily used variables; the variable is assigned to a high-speed CPU register (rather than an ordinary memory location)
- ❑ you cannot generate pointers to them using the & operator !
- ❑ **extern:**
 - ❑ reference to a variable with the same name defined at the external level in any of the source files of the program
- ❑ the identifier declared has its **defining** instance somewhere else
- ❑ used to make the external-level variable definition visible within the block

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ External variables – how to use them:

```
#include "prog01.h"

unsigned int u16Var1;
unsigned int u16Var2;
```

```
....
Declarations
Functions
....
```

prog01.c

```
.....
extern unsigned int u16Var1;
.....
```

prog01.h

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Variable scope

- The visibility of a declared variable is called the **variable's scope**; if a portion of a program lies outside a variable's scope then the compiler will give an error if you refer to the variable in that portion
 - For automatic variables declared at the beginning of a function, the scope is the function in which the name are declared
 - Local variables of the same name in different functions are unrelated
 - The same is true of the parameters of the function, which are in effect local variables

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Variable scope

- The scope of an **external** variable or function lasts from the point at which it is declared to the end of the file being compiled; the compiler does not allocate memory when it sees an extern variable declaration
- There must be only one definition of an external variable among all the files that make up the source program; other files may contain “extern” declarations to access it

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Variable scope

- What happens when scopes overlap? The most recently declared instance of a variable is used. If you declare a global variable called `temp` outside all statement blocks and a local variable called `temp` inside your `main()`, function, the compiler gives the local variable precedence inside `main()`.
- While the computer executes statements inside `main()`'s scope (or statement block), `temp` will have the value and scope assigned to it as a local variable. When execution passes outside `main()`'s scope, `temp` will have the value and scope assigned to it as a global variable

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Static variables

- the scope of the object is limited to the rest of the source file being compiled
- function names are global, visible to any part of the entire program
- a **static** function is invisible outside of the file in which it is declared
- function local variables can also be declared as **static**. These are local to the function, but they remain in existence after the function terminates its execution.
- **static** variables are allocated in the “global” memory space (heap)

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

❑ **Register variables**

- ❑ makes sense for heavily used variables
- ❑ *register* variables are to be placed in machine registers, which may result in smaller and faster programs
- ❑ obsolete, compilers are able to optimize the code without such hints

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

❑ Variable initialization

- ❑ global variables are guaranteed to be initialized to zero
- ❑ automatic and register variables have undefined initial values
- ❑ for explicitly initialized global variables the initializer must be a constant expression
- ❑ for automatic and register variables, the initializer is not restricted to being a constant. It may be any expression involving previously defined values, even function calls

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Example:

```
...  
int able;  
void main(void)  
{  
    long quickstart(void);  
    long r;  
    ...  
  
    able=17;  
    l=quickstart();  
    ...  
}
```

file01.c

```
...  
long quickstart(void)  
{  
    extern int able;  
    ...  
    /* do something with able */  
    ...  
    return result;  
}
```

file02.c

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Example

- When the file 1 is compiled, the variable *able* is marked as external, and memory is allocated for its storage. When the file 2 is compiled, the variable *able* is recognized to be external because of the *extern* keyword, and no memory is allocated for the variable
- All address references to *able* in file 2 will be assigned the address of *able* that was defined in file 1
- The example above in which the declaration

extern int able;

allowed access to *able* from the file 2 will not work if *able* had been declared as follows in file 1:

static int able;

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Data Types

- act as filters between your program and computer memory
- Type definition is used for:
 - the definition of the range of values
 - the size of memory (the amount of memory the computer must reserve for a value of that type)
 - the operations allowed
 - the scaling of pointers

ANSI C –Data Types

Why C?

□ Data types:

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

data type	size [in bytes]	range of values
void	undefined	none
signed char	1	-128 .. +127
unsigned char	1	0 .. 255
signed short	2	-32768 .. +32767
unsigned short	2	0 .. 65535
signed int	min. 2	compiler dependent
unsigned int	min. 2	
signed long	4	-2 147 483 648 .. +2 147 483 647
unsigned long	4	0 .. 4 294 967 295
float	4	+/-1.176e-38 .. +/-3,40e+38
double	8	+/-2,225e-308 .. +/-1,798e+308
pointers	1 .. 4	up to 32 bit addresses

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Data encapsulation - struct**

- encapsulates several data of different types that belong to the same object
- support the meaningful grouping of program data

▣ Syntax:

```
struct [struct_name]
{
    data_type1 ivar_list1;
    data_type2 ivar_list2;
    ...
} [svar_list];
```

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Data encapsulation - struct**

- ▣ **Example:** a structured type for the number shown by an LED display

```
struct Display_tag
{
    int DisplaySelected;
    int hundreds;
    int tens;
    int ones;
    char AorP;
};
```

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Data encapsulation - struct

- **Example (contd.):** the compiler allocates no memory for the structure declaration itself because it is used solely as a template for variable declarations. **When you declare a variable for a structure, the compiler will allocate an appropriate block of memory:**

struct Display_tag CurrentTime;

- You must repeat the keyword *struct* because *Display_tag* is not a valid data type, it is a structure tag

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Data encapsulation – struct**

- The access to a member of the structure is performed with the dot operator “.” and the structure pointer operator, “->”
- The order of the structure elements bears compiler specific consequences.
- Usually, data are aligned to even address boundaries.

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Data encapsulation – struct**

▣ If there is a structure declaration:

```
struct s1
{
    unsigned char cId;
    unsigned int iLength;
    unsigned char cMsg;
};
```

the compiler may reserve four, six, or even more bytes of memory, depending on the alignment

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Data encapsulation – struct

- alignment of structure members depends on the memory alignment of the system

byte number	byte aligned	word aligned
0	s1.sid	s1.sid
1	s1.size (low byte)	<hole>
2	s1.size (high byte)	s1.size (low byte)
3	s1.msg	s1.size (high byte)
4		s1.msg
5		<hole>

ANSI C –Data Types

Why C?

Example:

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

```
/* a structure for the number shown by an LCD display */
...
struct Display_tag * Display_Ptr;
struct Display_tag
{
    int DisplaySelected;
    int hundreds;
    int tens;
    int ones;
    char AorP;
}alarmTime;

...
void main()
{
    Display_Ptr = &alarmTime; //point Display_Ptr to alarmTime
    Display_Ptr->ones = 7; //set alarmTime.ones to 7
    Display_ptr->AorP = 'P'; //set alarmTime.AorP to P
    Display_Ptr->tens = 9; //set alarmTime.tens to 9
    (*Display_Ptr).tens = 9; //set alarmTime.tens to 9
}
```

file01.c

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Data encapsulation – **union**

- A union means an overlay of elements of different data types to the same memory location.
- Syntax:

```
union [union_name]
{
    data_type1 ivar_1;
    data_type2 ivar_2;
    ...
} [uvar_list];
```

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Data encapsulation – **union**

- The size of the union is determined by the size of its biggest member element

- **Example:**

```
union
{
    unsigned char c[2];
    long l;
} u1;
```

- The size of u1 is equivalent to the size of long (4 bytes). The lowest byte of u1 may now be accessed by u1.c[0] as well as by u1.l

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded

Examples

□ Data encapsulation – **union**

• Example (*contd*):

```
union
{
    unsigned char c[2];
    long l;
} u1;
```

byte number	accessed by	accessed by
0	u1.c[0]	u1.l (lowest byte)
1	u1.c[1]	u1.l
2		u1.l
3		u1.l (highest byte)

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- **Data encapsulation – union**
 - One common use of the union type in embedded systems is to create a scratch pad variable that can hold different types of data. This saves memory by reusing one 16 bit block in every function that requires a temporary variable

Example:

```
struct lohi_tag
{
    short lowByte;
    short hiByte;
};
union tagName
{
    int asInt;
    char asChar;
    short asShort;
    long asLong;
    int near * asNPtr;
    int far * asFPtr;
    struct hilo_tag asWord;
} scratchPad; //scratchPad is the variable name
...
// accesing union elements
union tagName * scratchPad_ptr; //declare pointer type
scratchPad_ptr = &scratchPad; //point to scratchPad
someInt = scratchPad_ptr->asInt; //retrieve as integer
scratchPad.asChar = 'b'; //assign b to scratchPad
tempChar = scratchPad.asChar; //retrieve as character
```

file01.c

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Data encapsulation – union

- Another common use for union is to facilitate access to data as different types. For example, the Microchip PIC16C74 has a 16 bit timer/counter register called TMR1 made up of two 8 bit registers called TMR1H (high byte) and TMR1L (low byte). It is possible that sometimes you would like to access the register as two 8 bit values or as one 16 bit value. A union will facilitate this type of data access:

- **Example:**

```
struct asByte
{
    int TMR1H; //high byte
    int TMR1L; //low byte
};
union TIMER1_tag
{
    long TMR1_word; //access as 16 bit register
    struct asByte TMR1_byte;
} TMR1;
```

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Bit fields

- offer the possibility to access single bits or groups of bits in the not bit addressable memory.
- The order of the bits can be defined with the help of the *struct* keyword:

```
struct [bitfield_name]
{
    data_type1 ivar_1: n_bit_1;
    data_type2 ivar_2: n_bit_2;
    ...
} [bitfield_list];
```

The Embedded
Difference

Examples

□ Bit fields

- **n_bit** is the size of the bit field element **ivar** in bits. Negative values are forbidden, values with more bits than that of the standard word width of the controller might lead to errors. A value of zero means that the current bitgroup fills up the remaining bits to the next word (=int) boundary.
- Bitfields are used especially in connection with control and status registers of the periphery of microcontrollers
- The ordering of the bits is compiler specific. This means that some compilers assign the LSBs to the first bits of the bit field definition, while others use the MSBs

ANSI C –Data Types

□ Bit fields – Example 1

```
struct TxIC
{
    unsigned int glvl: 2;
    unsigned int ilvl: 4;
    unsigned int ie: 1;
    unsigned int ir: 1;
    unsigned int : 0;
} t7ic;
t7ic.ilvl = 12;
```

- The compiler will assign the bits as given below:

bit-no.	15 - 8	7	6	5 - 2	1 - 0
bit name	?	ir	ie	ilvl	glvl
binary value				1100

ANSI C –Data Types

Bit fields – Example 2

- for the Motorola MC68HC705C8 defines the Timer Control Register (TCR) bits as bit fields in the structure called TCR

```
struct reg_tag
{
    int ICIE : 1; // field ICIE 1 bit long
    int OCIE : 1; // field OCIE 1 bit long
    int notUsed : 3 = 0; //notUsed is 3 bits and set to 0
    int IEDG : 1; // field IEDG 1 bit long
    int OLVL : 1; // field OLVL 1 bit long
} TCR;

...
struct reg_tag * TCRFieldPtr;
TCRFieldPtr = &TCR;
TCR.ICIE = 1; // access using dot operator
TCRFieldPtr->ICIE = 1; // using right arrow operator
```

The Embedded
Difference

Examples

□ Enumerated data types

- The most straightforward complex data type is the enumerated data type, declared as type *enum*. The *enum* type is used to represent a set of possible values.

- Syntax:

```
enum [enum_name]
{
    value_1 [= ival]
    [,value_2 [= ival]]
    ...
} [enum_list];
```

ival is the value that **value_x** shall be represented with. If not specified value_1 will be assigned 0, value_2 = 1, etc.

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Enumerated data types

■ Observations

- Internally, an *enum* variable is treated as a signed integer
- The compiler does not check the variable against the defined values of the enumeration value list
- *enum* variables should only be used in assignment and comparison operations
- Enumerated values can be used as if they were defined as a macro, what means that they are known at compile time and can thus be used in SWITCH-CASE statements

ANSI C –Data Types

□ Enumerated data types - Examples:

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- creates an enumerated type called WEEK, provides seven possible values, and declares a variable called dayOfWeek of this new enumerated type.
`enum WEEK { Su, Mo, Tu, We, Th, Fr, Sa } dayOfWeek;`
- separate this process into two declarations
`enum WEEK { Mo, Tu, We, Th, Fr, Sa, Su };`
`enum WEEK dayOfWeek; // WEEK is called a tag`
- The tag is useful as it can represent a list of enumerated elements to declare more than one variable of that type
`enum WEEK { Su, Mo, Tu, We, Th, Fr, Sa } dayOfWeek;`
`enum WEEK dayOFWeek;`
`enum WEEK payDay = Th;`
`enum WEEK groceryDay = Sa;`

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Definition of private types

- **struct**, **union**, and **enum** keywords allow both type declaration and data definition in one statement
- in order to separate declaration and definition, the **typedef** keyword can be used

- **syntax:**

`typedef basic_type type_name;`

where:

- **typedef** “C”-keyword for data structure declaration
- **basic_type** may be any type such as char, int, float, struct, union, enum, etc
- **type_name** is any name allowed

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- **Definition of private types**
 - Useful type definitions:
 - `typedef unsigned char uint8;`
 - `typedef signed char int8;`
 - `typedef unsigned int uint16;`
 - `typedef signed int int16;`
 - `typedef unsigned long uint32;`
 - `typedef signed long int32;`
 - the above type definitions allow writing platform-independent code

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Type Conversion**

- Implicit type conversion
- Explicit type conversion

□ **Implicit type conversion**

- when operands of different types are combined in expressions
- the conversions are implicitly performed according to standard rules

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Type Conversion**

▣ **Implicit cast**

- all char and short operands are converted to int
- if one operand is unsigned, the other operand is converted to unsigned as well
- all float operand are converted to double
- if the operand of an expression are of different types, calculations always occur with the widest type. (Width of a data type simply means the number of bytes a value occupies.
- the result of an expression is always adjusted to the type of variable the result has.

ANSI C –Data Types

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Type Conversion**

▣ **Implicit cast – Example:**

```
char v1;
```

```
int v2;
```

```
double v3;
```

```
v2 = v1+v3; /*expression is double, result is int*/
```

```
v1 = v2 - 2*v1; /* expression is int. The result  
variable is of type char. The most  
significant part of result is lost */
```

ANSI C –Data Types

□ Type Conversion

□ Explicit cast

- to avoid hidden code which might lead to wrong results, every type conversion must be casted explicitly.
- explicit cast is expressed by writing the desired data type in parenthesis as an operator in front of them

■ Example:

```
unsigned int i1;
```

```
char c1, c2;
```

```
c1 = (char)(i1 - (int)c2);
```

```
/* there is a value range reduction by casting the expression  
as char */
```

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Binary operators. Bitwise (bit-by-bit) operations**

- **&** is often used to clear one or more bits of an integral variable to 0.

```
PTH = PTH & 0xBD           // clears bit 6 and bit 1 of PTH to 0
```

```
// PTH is of type char
```

- **|** is often used to set one or more bits to **1**

```
PTB = PTB | 0x40;           // sets bit 6 to 1 (PTB is of type char)
```

- **^** can be used to toggle a bit.

```
abc = abc ^ 0xF0;           // toggles upper four bits (abc is of type char)
```

ANSI C – Assignment, Expression, Operators

□ Binary operators. Bitwise (bit-by-bit) operations

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- `>>` can be used to shift the involved operand to the right for the specified number of places. For unsigned numbers, the bit positions that have been vacated by the shift operation are zero-filled. For signed numbers, the sign bit is used to fill the vacated bit positions. In other words, if the number is positive, 0 is used, and if the number is negative, 1 is used

`xyz = xyz >> 3;` -- shift right 3 places

- `<<` can be used to shift the involved operand to the left for the specified number of places. The bit positions that have been vacated by the shift operation are zero-filled.

`xyz = xyz << 4;` -- shift left 4 places

- The assignment operator `=` is often combined with the operator. For example,

`PTH &= 0xBD;`

`PTB |= 0x40;`

`xyz >>= 3;`

`xyz <<= 4;`

ANSI C – Assignment, Expression, Operators

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- **Binary operators. Bitwise (bit-by-bit) operations**
 - multiplication and divisions can be avoided for operands of value $2x$, what results in a faster code.

- **Example:**
 - 1. $z = x * 2;$ \Rightarrow $z = x \ll 1;$
 - 2. $z = x / 2;$ \Rightarrow $z = x \gg 1;$

- **there is no overflow checking mechanism available!**

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Operators**

□ **Examples:**

▣ `x = x | MASK;` all bits of x which are set in MASK are set

▣ `n = ~ n;` negation of bits

▣ `res = status & (~1);` clear the bit 0

ANSI C – Assignment, Expression, Operators

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Operators**

- Increment and decrement operators can be used in prefix or postfix notation. They must not be used for expressions.

- An increment/decrement of pointers is type specific

□ **Example:**

```
long *i_ptr = 0x100;
```

```
i_ptr++; // i_ptr points to 0x104
```

ANSI C – Assignment, Expression, Operators

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Operators**

- The order of unary operations is important as this may affect the result.

□ **Example:**

```
unsigned char a = 0x7f;
```

```
unsigned int b1, b2;
```

```
b1 = (unsigned int)~a; // b1 = 0x0080;
```

```
b2 = ~(unsigned int)a; // b2 = 0xff80;
```

ANSI C – Assignment, Expression, Operators

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Operators**

- The modulo operation works for integer-by-integer divisions only. It returns the integer remainder.
- Instead of the conditional operator, an if-...construct should be used,

□ **Example:**

`x = (a ? 1 : 0);` should be replaced by
`if (a) x=1;`
`else x=0;`

ANSI C – Assignment, Expression, Operators

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Logical expressions**

- It is rare for logical values to be stored in variables
- They are usually generated as required by comparing two numeric values
- they are evaluated from the left to the right
- in order to reduce calculation time, put to the first place the most unlike condition in an **AND** connection (&&) and the most probable condition in an **OR** connection (||).

Program Flow Statements

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Sequences

- Single Branching: The “if”-Statement
- Double Branching: The “if-else”-Statement
- Multiple Branching: The “switch - case”-Statement
- Loop with Testing in the Beginning: The “while”-Statement
- Indexed Loop with Testing in the Beginning: The “for”-Statement
- Loop with Testing in the End: The “do - while”-Statement
- Other Program Flow Statements: continue, break, goto

Program Flow Statements

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Single Branching: The “if”-Statement

if (*expression*)
sequence

- Only if the boolean **expression** in parenthesis evaluates to logical TRUE, the **sequence** will be executed
- To compare an *unsigned int* variable with unlike 0 the following syntax should be preferred :

if (var != 0) or *if (var)* instead of *if (var>0)*

Program Flow Statements

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Double Branching: The “if-else“-Statement

```
if ( expression )  
    sequence_1  
  
else  
    sequence_2
```

- the expression should be formulated so that the most probable result is TRUE. Then, most often the branch to **sequence_2** may not be taken, which results in a shorter program execution time.
- encapsulation of several “if - else“ statements can be avoided by using boolean algebra:

```
if ( expression_1 || ( expression_2 && expression_3 ) )  
    sequence_1
```

Program Flow Statements

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Multiple Branching: The “switch - case“-Statement**

```
switch ( expression )  
{  
    case const_expression_1: statement_1; break;  
    ...  
    case const_expression_n: statement_n; break;  
    default: statement_n+1; break;  
}
```

- **expression** will be evaluated. The result is of type **int** or **unsigned int**

Program Flow Statements

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- **Multiple Branching: The “switch - case“-Statement**
- **const_expression** must be a constant value which is known at compile time. If the **expression** in parenthesis matches the **const_expression**, the subsequent statements are evaluated up to the next break statement respectively the end of the block.
- The order of the constant expressions should be chosen according to the plausibility of their occurrence for runtime reasons.

Program Flow Statements

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- **Multiple Branching: The “switch - case“-Statement**
- **break** “C“-keyword that causes leaving the actual block. Every **case** should have a **break** statement.
- **default** is a predefined label for all cases that do not match any of the other constant expressions in the block. In ANSI-“C“ it may be missing, which however means a bad programming style.
- put the cases in the order according to their probability because the compiler sometimes generates an assembly code which rather reflects an if ... elseif ... else structure, especially if only few cases are given

Program Flow Statements

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ The “while”-Statement

`while (expression)`

`sequence`

- The condition given by **expression** is evaluated first. Only if the result is TRUE the sequence is executed. It will be repeated as long as the **expression** is TRUE.
- Potentially endless loops must be equipped with a software watchdog:

```
while (*int_ptr <= TopValue && special_exit == 0);
```

Program Flow Statements

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ The “for“-Statement

for (*[init_list]* ; *[expression]*; *[continue_list]*)
sequence

- **init_list** is a list of statements separated by commas which will be executed unconditionally in advance of the loop.
- **expression** results in a boolean value TRUE or FALSE. As long as it is TRUE, the **sequence** is executed, followed by the statements of the **continue_list**.
- **continue_list** is a list of statements separated by commas which are evaluated as long as the **expression** is TRUE.

Program Flow Statements

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ The “for“-Statement

- The loop control variable must only be changed in the **continue_list** but nowhere else.
- Likewise, the loop exit condition must only be checked in the **expression**.
- To compare a decreasing local counter with unlike 0 the following syntax should be used:

`for (i = 10; i > 0; i--)` instead of `for (i = 10; i != 0; i--)`

Program Flow Statements

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ The “do - while“-Statement

do

sequence

while (*expression*);

- The **sequence** is executed at least once. After that the **expression** is evaluated, and the **sequence** is repeated as long as it's result is TRUE.

Program Flow Statements

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Other Program Flow Statements

- goto
- continue
- break
- **goto must** and the other two instructions **should** be avoided as they lead to an ill structured program flow
- **goto** causes the program to continue at the label which is defined at any other place in the program by a subsequent colon.

Program Flow Statements

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Other Program Flow Statements

- **continue** is used in loop constructs and means a shortcut to continue with testing the next loop condition. Therefore, the statements following the **continue** statement won't be executed.
- **break** statement causes the program to continue at the next label outside the current block. It should be used in connection with **switch - case** constructs but not otherwise.

Arrays, Pointers

Why C?

Examples

□ Arrays

□ Pointers

- ▣ Pointers scaling
- ▣ Pointers and Function Arguments
- ▣ Pointers and Arrays
- ▣ Pointers vs.. Multi-dimensional Arrays

□ Functions

- ▣ Function Header
- ▣ Function Body
- ▣ Calling a function

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Arrays**

- Encapsulate multiple elements of a single data type with one variable name.
- No checking mechanism for the boundaries
- Index must be of an unsigned type
- Data are contiguously allocated

Array Declaration:

`<type> <name> [<size>;`

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Arrays

- **type** could be any type;
- **size** is mandatory: it's the maximal number of elements in the array
- The declaration is going to allocate enough bytes for the whole array
- Array could be initialized when declaring :
 - `<type> <name> [<optional size>] = { <value list> }`
- in this case, the **size** is optional (if the size is not given, the size of the array is set to the number of element in the declaration list)

Arrays, Pointers

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Pointers

- Are **variables that contain the address of an object (variable or function).**
- Enable indirect access to an object.
- Are defined with the **dereference operator (*)**

□ Definition:

*type * pointer_name;*

- **type** is the type of the object the pointer points to.
- **pointer_name** is a free choosable name of the pointer.

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Pointers

```
unsigned u16Val;
```

```
unsigned *p = &u16Val;
```

```
....
```

p is 0x0186 (address of
u16Val)

*p is 0x55AA; (value
located at address
0x0186, the value of
u16Val)

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Pointers

- A pointer can take the value of another pointer, **an address of an object** with “**address-of**” operator **&**, or a pointer expression

```
char *p ; int *q;
```

```
char a; int b;
```

```
p = &a; /*correct*/
```

```
p = &b; /* incorrect */
```

```
q = &a; /* incorrect */
```

```
q = &b ; /* correct */
```

```
p = &q; /* address of the pointer */
```

Arrays, Pointers

Why C?

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Pointers**

- Const keyword can be used in pointer declarations.

□ **Example:**

```
int a;  
int *p;  
int *const ptr = &a;    // Constant pointer  
*ptr = 1;               // Legal  
ptr = p;                // Error
```

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Pointers

- A pointer to a variable declared as const can only be assigned to a pointer that is also declared as const.

□ Example:

```
int a; int *p; const int *q;  
const int *ptr = &a;    // Pointer to constant data  
*ptr = 1;                // Error  
ptr = p;                 // Error  
ptr = q;                 // Legal
```

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Pointers scaling

- The type of the object a pointer points to serves the compiler as a basis for relative address calculations using pointer addition, subtraction, increment, and decrement.

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- **Pointers scaling**

- **Example:**

```
long *sl_ptr = 0x4000;  
char *sc_ptr;  
sc_ptr++ = (char *)(sl_ptr + 2);
```

will result in

```
tmp = sl_ptr + 2*sizeof(long)  
    = 0x4000 + 2*4  
    = 0x4008                                => sc_ptr  
sc_ptr++ = 0x4008 + 1*sizeof(char)  
        = 0x4008 + 1*1  
        = 0x4009                                => sc_ptr
```

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Pointers and Function Arguments

- Pointer arguments enable a function to access and change objects in the function that called it. For instance, a sorting routine might exchange two out-of-order elements with a function called swap:

```
swap(&a, &b);
```

- Since the operator **&** produces the address of a variable, **&a** is a pointer to **a**.
- the parameters are declared to be pointers, and the operands are accessed indirectly through them.

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Pointers and Function Arguments

```
void swap(int *px, int *py) /* interchange *px and *py */
{
    int temp;
    temp = *px;
    *px = *py;
    *py = temp;
}
```

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Pointers and Arrays**

- Any operation which can be achieved by array subscripting can also be done with pointers.
- The pointer version will in general be faster

□ The declaration

int a[10]

defines an array a of size 10, that is a block of 10 consecutive objects named a[0], a[1], ..., a[9].

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded

Difference

Examples

□ Pointers and Arrays

- The notation **a[i]** refers to the **i**-th element of the array. If **pa** is a pointer to an integer, declared as

int *pa

then the assignment

pa = &a[0];

sets **pa** to point to element zero of **a**:

pa contains the address of **a[0]**.

Now the assignment **x = *pa** will copy the contents of **a[0]** into **x**.

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Pointers and Arrays

- If **pa** points to a particular element of an array, then by definition:
 - ▣ **pa+1** points to the next element, **pa-i** points **i** elements before **pa**, and
 - ▣ **pa+i** points **i** elements after.

Thus, if **pa** points to **a[0]**, then ***(pa+1)**

refers to the contents of **a[1]**, **pa+1** is the address of **a[i]**, and ***(pa+i)** is the contents of **a[i]**.

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Pointers and Arrays

- By definition, the value of a variable or expression of type array is *the address of element zero of the array*. Thus after the assignment

`pa = &a[0]`

`pa` and **`a`** have identical values

- The assignment **`pa=&a[0]`** can also be written as **`pa = a;`**

Arrays, Pointers

Examples

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Arrays of Pointers

- The most common use for an array of pointers is to use an array of pointers to type char which are pointed to strings. This technique can be used to send messages to a screen.

■ the array is declared in main but the array is passed to a function where the values of the pointers are assigned

(about functions – a little bit later 😊)

```
void func1(char *p)
{
    p[0]="Press 1 to start";
    p[1]="Press 2 to continue";
    p[2]="Press 3 to RESET";
    p[3]="Press 4 to quit";
}
void main(void)
{
    int val;
    char *message[10];
    if (val==TRUE)
    {
        func1(message);
    }
    else
        message[0]="Status is OK";
}
```

file01.c

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Pointers vs. Multi-dimensional Arrays

- Given the declarations

```
int a[10][20];
```

```
int *b[10];
```

- Array **a** is a true two-dimensional: 200 int-sized locations have been set aside, and the calculation **$20 \times \text{row} + \text{col}$** is used to find the element **$a[\text{row}, \text{col}]$**
- For **b**, the definition only allocates 10 pointers and does not initialize them; initialization must be done explicitly, either syntactically or with code.

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Pointers vs. Multi-dimensional Arrays

```
char array [3][12] = {"The Course\n",  
                      "is\n",  
                      "boring\n"};
```

array[2]

array[1]

array[0]

b	o	r	i	n	g	\n	\0				
i	s	\n	\0								
T	h	e		C	o	u	r	s	e	\n	\0

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Pointers vs. Multi-dimensional Arrays

```
char *array[] = {"The Course\n",  
                 "is\n",  
                 "boring\n"};
```

array[2]	b	o	r	i	n	g	\n	\0				
array[1]	i	s	\n	\0								
array[0]	T	h	e		C	o	u	r	s	e	\n	\0

Advantage of the pointer array is that the rows of the array may be of different lengths. That is, each element of **b** need not point to a twenty-element vector; some may point to two elements, some to fifty, and some to none at all

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Pointer to Strings**

- C does not know string, only arrays of characters.
- for the processing of strings, (searching, comparing, copying), standard routines exist.
- to be able to use subprograms, pointers to strings are used when passing parameters. The whole processing of strings relies on the use of pointers

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ **Pointer to Strings**

- the incrementing of a pointer on characters shifts the pointer to the next valid element of the string.

```
char *text, character;  
text = "C - tutorial";  
character = *(text+4);
```

Arrays, Pointers

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

□ Pointers

- only a small selection of operations are defined for pointers:

Operation	Sign	Examples:
		<code>int *iptr, *jptr; unsigned int offset, tmp;</code>
Assignment	=	<code>iptr = 0x4000; jptr = iptr;</code>
Increment	++	<code>iptr++;</code>
Decrement	--	<code>--jptr;</code>
Comparison	<code>== != <= >= < ></code>	<code>if (iptr >= 0x2000); tmp = (jptr != iptr);</code>
Addition	+	<code>jptr = iptr + offset;</code>
Subtraction	-	<code>jptr = iptr - 0xf800u;</code>
Pointer Distance	-	<code>tmp = iptr - jptr;</code>

Examples

- Macro definition
- File inclusion
- Conditional compilation
- Memory model

Preprocessor directives

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- preprocessing is scheduled before compilation process
- It mainly consist in a text analyzing and processing tool. The produced file is used as input for compilation process
- the goal: flexible software for different application parameters and different software development tools
- preprocessor directives always start with **#** character in the first column line

Preprocessor directives

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

#define

introduces the definition of a preprocessor macro

#undef

clears a preprocessor macro definition

#include

includes the source text of another file

#if

evaluates an expression for conditional compilation.

#ifdef

checks for conditional compilation whether a macro is defined

Preprocessor directives

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

#ifndef: checks for conditional compilation whether a macro is not defined

#elif: introduces an alternative #if branch following a not compiled #if, #ifdef, #ifndef or #elif branch

#else: introduces an alternative branch following a not compiled #if, #ifdef, #ifndef or #elif branch

#endif: completes a conditional compilation branch

#line: indicates the line number and, optionally, a file name which is used in error logging files to identify the error position.

#error: reports an error which is determined by the user

Preprocessor directives

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

#pragma

Inserts a compiler control command.

Options for the compilation can be given just as in the command line.

A **#pragma** directive not known to the compiler is ignored and leads to a portable code.

Preprocessor directives

Why C?

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

Macro definitions

```
#define Macro_Name [ [(parameters)] replace_text]
```

#define: preprocessor directive

Macro_Name: is the name of the macro. Will be substituted by `replace_text`.

parameters: used literally in the `replace_text` and replaced when the macro is expanded

replace_text: the given text will replace the macro call literally

Preprocessor directives

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

It is forbidden to define macro with side effect (eg. increment) - disturbs the error checks consistency.

String operator: **#**

- is used in the `replace_text` to induce that the subsequent string is interpreted as the name of parameter. This name is replaced at the time the macro is expanded.

Token-pasting operator: **##**

- precedes or follows a formal parameter. When it is expanded, the parameter is concatenated with the other text of the token.

Preprocessor directives

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

Files inclusion

```
#include <file_name>
```

```
#include "file_name"
```

Additional information can be used in a source file (data types, function prototypes, ...) => header files.

“...” - source file path is the first path where the include file is searched. If it can not be found there, the project specific include path will be inspected.

<...> - omits the current source path and start the search of the include search path of the project.

Preprocessor directives

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

Files inclusion

- Some problem might arise if a header file defines some symbols and is included in multiple modules. The content of a header file must be delimited by a preprocessor switch
- Solution:

```
#ifndef __HEADER_FILE_H__
```

```
#define __HEADER_FILE_H__
```

```
.....
```

```
header-file content
```

```
.....
```

```
#endif
```

Miscellaneous Items

	Input and Output	Examples
Why C?		
ANSI C		
Introduction	<ul style="list-style-type: none">- Not part of the C language itself.- Four I/O functions will be discussed.	
Identifiers		
Data Types	<ol style="list-style-type: none">1. <code>int getchar ()</code>. -- returns a character when called	<pre>char xch; xch = getchar ();</pre>
Expressions		
Program flow	<ol style="list-style-type: none">2. <code>int putchar (int)</code>. -- outputs a character on a standard output device	<pre>putchar('a');</pre>
Arrays & Pointers		
Functions	<ol style="list-style-type: none">3. <code>int puts (const char *s)</code>. -- outputs the string pointed by <code>s</code> on a standard output device	<pre>puts ("Hello everyone :) ! \n");</pre>
Preprocessor		
The Embedded Difference		
Examples	<ol style="list-style-type: none">4. <code>int printf (formatting string, arg1, arg2, ...)</code>. -- converts, formats, and prints its arguments on the standard output device.	

Miscellaneous Items

Formatting String for Printf

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- The arguments of ***printf*** can be written as **constants, single variable or array names**, or more complex expressions.
- The formatting string is composed of individual groups of characters, with one character group associated with each output data item.
- The character group starts with **%**.
- The simplest form of a character group consists of the percent sign followed by a *conversion character* indicating the type of the corresponding data item.
- Multiple character groups can be contiguous, or they can be separated by other characters, including whitespace characters. These “*other characters*” are simply sent to the output device for display.

- **Examples:**

```
printf ("this is a challenging course ! \n");  
printf ("%d %d %d", x1, x2, x3); // outputs x1, x2, and x3 using minimal number  
                                // of digits with one space separating each value  
printf ("Today's temperature is %4.1 d\n", temp);
```

Miscellaneous Items

Using the C Compilers

- The special edition C compiler from **CodeWarrior** has a size limit of 32 kB.
- The demo version of **ImageCraft C** compiler has a size limit of 8 kB.
- The **GNU C compiler** does not have size limit but the **EGNU IDE** cannot program flash memory which limits it to download program into the on-chip SRAM only.

Accessing Peripheral Registers

- Depending on the size of a peripheral register, it can be declared in one of the following methods:

```
#define reg_name *(volatile unsigned char *) reg_addr // 8-bit wide register
#define reg_name *(volatile unsigned int *) reg_addr // 16-bit wide register
```

- The HCS12 allows all of the peripheral registers to be relocated as a block. For this reason, the ImageCraft uses the following method to define peripheral registers:

```
#define reg_base 0x0000 // base address
#define reg_name1 *(volatile unsigned char *) (reg_base + offset1)
#define reg_name2 *(volatile unsigned int *) (reg_base + offset2)
```

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

```
#define      IOREGS_BASE  0x0000

#define      _IO8(off)    *(unsigned char volatile *)(IOREGS_BASE + off)

#define      _IO16(off)   *(unsigned short volatile *)(IOREGS_BASE + off)

#define      PORTA        _IO8(0x00)    // port A data register

#define      PTA          _IO8(0x00)    // alternate name for PORTA

#define      ATD0DR0      _IO16(0x90)   // ADC result 0 register (a 16-bit register)
```

Peripheral Register Bit Definitions

- A value is assigned to each bit in the peripheral register that represents its weight.
- For example, the ADPU bit of the ATD0CTL2 register is defined to be 0x80 that is the positional weight (bit 7) of this bit. It is defined as follows:

```
ADPU equ     $80
```

This bit can be set using the following statement:

```
ATD0CTL2 |= ADPU;
```

C Programming Style

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- Programming style refers to **a set of rules and guidelines** used when writing a program.
- The essence of good programming style is **communication**.
- The objective of a good programming style is to make the program **easy to understand and debug**.
- A programmer uses three primary tools to communicate their intentions: comment, **naming of** variables, constants, and functions, and **program appearance** (spacing, alignment, and indentation).

General Guidelines to Comments

- The programmer should explain what every function does, what every variable does, and every tricky expression or section of code.
- The comment should be added before the programmer defines a variable or writing a function or section of code.
- Avoid obscure programming language constructs and reliance on language-specific precedence rules.

Miscellaneous Items

Program Documentation

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

All programs should include, at the beginning of the program, a comment block that

Includes at least:

- The programmer's name
- The date of creation
- The operating system and IDE for which the program was written
- Hardware environment (circuit connection) to run the program
- Program structure (organization)
- Algorithm and data structures of the program
- How to run the program

An Example is in the next page:

Miscellaneous Items

Why C?	// -----
ANSI C	// Program: RtiMultiplex7segs
Introduction	// Author: Some Name
Identifiers	// Build Environment: CodeWarrior IDE under Windows XP
Data Types	// Date: 07/09/2008
Expressions	// Hardware connection: short description
Program flow	// Operation: This program shifts seven-segment patterns of 4 consecutive BCD digits
Arrays & Pointers	// by using time-multiplexing technique with each pattern lasting for 0.5 s. The
Functions	// time-multiplexing operation is controlled by the real-time interrupt. The patterns are
Preprocessor	// 1 2 3 4
The Embedded	// 2 3 4 5
Difference	// 3 4 5 6
Examples	// 4 5 6 7
	// 5 6 7 8
	// 6 7 8 9
	// 7 8 9 0
	// 8 9 0 1
	// 9 0 1 2

Miscellaneous Items

Function Documentation

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- Every function should be preceded by a comment describing the purpose and use of that Function. An example is as follows:

```
//-----  
// Function: FindSquareRoot  
// Purpose: Computes and returns the square root of a 32-bit unsigned integer  
// Parameter: A 32-bit unsigned integer of which the square root is to be found  
// Called by: PrimeTest()  
// Returned value: the square root of a 32-bit unsigned integer  
// Side effects: none  
//-----
```

Code Appearance

Program readability can be improved by

- Proper spacing
- Proper indentation
- Vertical alignment

Miscellaneous Items

Proper Spacing

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

for (i=0;i<15;i++) & for (i = 0; i < 15; i++)
easier to read

Proper Indentation

- The following code is hard to read without proper indentation:

```
while(TRUE) {  
    for (i = 0; i < 10; i++) { // pattern array start index  
        for (j = 0; j < 100; j++) { // repeat loop for each pattern sequence  
            for (k = 0; k < 6; k++) { // select the display # to be lighted  
                PTB      = SegPat[i+k]; // output segment pattern  
                PTP      = digit[k];    // output digit select value  
                delayby1ms(1); // display one digit for 1 ms  
            }  
        }  
    }  
}
```

Miscellaneous Items

Proper Spacing, Proper indentation

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

With proper indentation, the code section becomes easier to read:

```
while(TRUE) {  
    for (i = 0; i < 10; i++) {           // pattern array start index  
        for (j = 0; j < 100; j++) {      // repeat loop for each pattern sequence  
            for (k = 0; k < 6; k++) {    // select the display # to be lighted  
                PTB    = SegPat[i+k];    // output segment pattern  
                PTP    = digit[k];       // output digit select value  
                delayby1ms(1);           // display one digit for 1 ms  
            }  
        }  
    }  
}
```

Miscellaneous Items

Vertical Alignment

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- It is often helpful to align similar elements vertically, to make typo-generated bugs more obvious.

- Compare the next two sections of code. It is obvious that the second one is easier to identify errors:

```
// values to generate 1 cycle of sine wave
unsigned rom char upper[60] = {0x38, 0x38, 0x39, 0x3A, 0x3B, 0x3C,
    0x3C, 0x3D, 0x3D, 0x3E, 0x3E, 0x3F, 0x3F, 0x3F, 0x3F,
    0x3F, 0x3F, 0x3F, 0x3F, 0x3F, 0x3E, 0x3E, 0x3D, 0x3D,
    0x3C, 0x3C, 0x3B, 0x3A, 0x39, 0x38, 0x38, 0x37, 0x36, 0x35, 0x34, 0x34,
    0x33, 0x32, 0x32, 0x31, 0x38, 0x37, 0x36, 0x35, 0x34, 0x34,
    0x30, 0x30, 0x30, 0x30, 0x30, 0x31, 0x31, 0x32, 0x32, 0x33,
    0x34, 0x34, 0x35, 0x36, 0x37};
```

(a) non-vertically aligned array

```
// values to generate 1 cycle of sine wave
unsigned rom char upper[60] = {
    0x38, 0x38, 0x39, 0x3A, 0x3B, 0x3C, 0x3C, 0x3D, 0x3D, 0x3E,
    0x3E, 0x3F, 0x3F, 0x3F, 0x3F, 0x3F, 0x3F, 0x3F, 0x3F, 0x3F,
    0x3E, 0x3E, 0x3D, 0x3D, 0x3C, 0x3C, 0x3B, 0x3A, 0x39, 0x38,
    0x38, 0x37, 0x36, 0x35, 0x34, 0x34, 0x33, 0x32, 0x32, 0x31,
    0x31, 0x30, 0x30, 0x30, 0x30, 0x30, 0x30, 0x30, 0x30, 0x30,
    0x31, 0x31, 0x32, 0x32, 0x33, 0x34, 0x34, 0x35, 0x36, 0x37};
```

(b) vertically aligned array

Figure 5.39 Influence of vertical alignment of array on readability

Miscellaneous Items

Naming of Variables, Constants, and Functions

Why C?

ANSI C

Introduction

Identifiers

Data Types

Expressions

Program flow

Arrays & Pointers

Functions

Preprocessor

The Embedded
Difference

Examples

- The names of variables, constants, and functions should spell out their meaning or purpose.
- A variable name may have one word or multiple words. Use lowercase when the name contains only one word. For example, **sum**, **limit**, and **average**.
- A multiple-word variable name should be in mixed case starting with lowercase.
For example, **inBuf**, **outBuf**, **squareRoot**, and **arrayMax**.
- Function names should follow the same principle. A few examples follow:
sevenSegShift(), **putcSPI()**, **putsSPI()**, **openLCD()**, and **putsLCD()**
- Named constants should be all uppercase using underscore (_) to separate words.
SONG_TOTAL_NOTES, **HI_DELAY_COUNT**, **LO_DELAY_COUNT**

The Embedded Difference

Why C?

ANSI C

The Embedded
Difference

Examples

- Most embedded systems programs include a header file which describes the target processor
- The header files contain descriptions of reset vectors, ROM and RAM size and location, register names and locations, port names and locations, register bit definitions and macro definitions
- Most compiler companies will provide header files for devices supported by their compilers
- **Example: for MC9S12DJ256**
`#include "mc9s12dj256.h"`

The Embedded Difference

Why C?

ANSI C

The Embedded
Difference

Examples

- Another important aspect of device knowledge is the limits of the device for which the program is written.
- A certain device may have very limited memory resources and great care must be taken in developing programs which use memory frugally
- Along with issues of size comes issues of speed. Different devices run at different speeds and use different techniques to synchronize with peripherals
- It is essential that you understand device timing for any embedded systems application

The Embedded Difference

Why C?

ANSI C

The Embedded
Difference

Examples

- Embedded systems developers require direct access to registers such as the accumulator
- The regular use of the infinite loop `while(1)`. Embedded developers often use program control statements which are avoided by other programmers

- **Example:**

```
while (1)
{
    if (PortA.1 == PUSHED)
    {
        PortA.0 = ON;
        wait(10); // wait ten seconds
        PortA.0 = OFF;
    }
}
```

The Embedded Difference

Why C?

ANSI C

**The Embedded
Difference**

Examples

- Techniques used in an embedded system program are often based upon knowledge of specific device or peripheral operation
- **Example:**
 - ▣ When a button is pressed it “bounces” which means that it is read as several pushes instead of just one
 - ▣ It is necessary to include debouncer support in order to ensure that a real push has occurred and not a bounce
 - ▣ **Solution:** a `wait()` function which creates a delay before the button is checked again

The Embedded Difference

Why C?

ANSI C

The Embedded
Difference

Examples

- Many developers prefer to write some code segments in assembly language for reasons of code efficiency or while converting a program from assembly language to C
- The following two definitions of the wait() function show the function written in C and the equivalent function in Motorola 68HC705C8 assembly language
- **#asm vs. #endasm**

The Embedded Difference

Why C?

ANSI C

The Embedded
Difference

Examples

□ **Example:**

MC68HC705C8

```
void wait(register delay)
{
    while (--delay);
}

//function with inline assembly
void wait(register)
{
    char temp, time;
    // ocap_low and Ocap_hi are the output compare register
    //this register is compared with the counter and the ocf
    //bit is set (bit 6 of tim_stat)
    #asm
    STA time ;store A to time
    LDA #$A0 ;load A with A0
    ADD ocap_low ;add ocap_low and A
    STA temp ;store A to temp
    LDA #$25 ;load A with 25
    ADC ocap_hi ;carry + ocap_hi + accumulator
    STA ocap_hi ;store A to ocap_hi
    LDA temp ;load temp to accumulator
    STA ocap_low ;store a to ocap_lo
    LOOP BRCLR 6,tim_stat,LOOP ;branch if OCF is clear
    LDA ocap_low ;load ocap_lo to A
    DEC time ;subtact 1 from time
    BNE LOOP ;branch if Z is clear
    #endasm
}
```

The Embedded Difference

Why C?

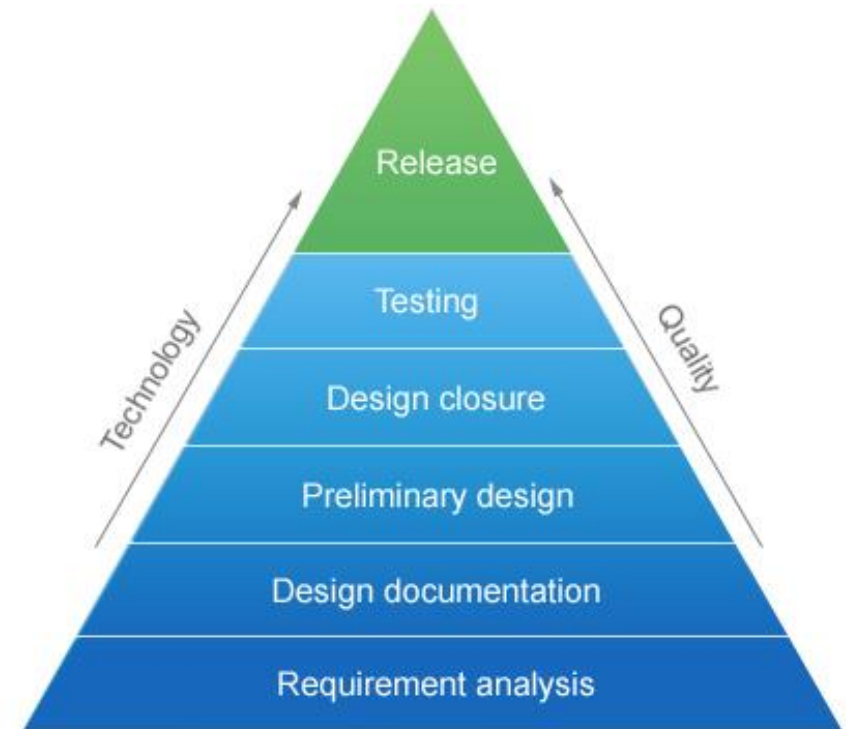

ANSI C

**The Embedded
Difference**

Examples

- **Embedded SW Development**

- 1. Problem specification
- 2. Tool/chip selection
- 3. Software plan
- 4. Device plan
- 5. Code/debug
- 6. Test
- 7. Integrate

- Biggest mistake: “temptation of the keyboard”
- Use of development processes

The Embedded Difference

Why C?

ANSI C

The Embedded
Difference

Examples

□ Embedded SW Development

- ▣ 1. Problem specification
- The problem specification is a statement of the problem that your program will solve without considering any possible solutions. The main consideration is explaining in detail what the program will do.
- Once the specification of the problem is complete you must examine the system as a whole. At this point you will consider **specific needs such as those of interrupt driven or timing-critical systems.**
- **Example:** If the problem is to design a home thermostat the problem specification should examine the functions needed for the thermostat. These function may include **reading the temperature, displaying the temperature, turning on the heater, turning on the air conditioner, reading the time, and displaying the time.** Based on these functions it is apparent that the thermostat will require hardware to sense temperature, a keypad, and a display.

The Embedded Difference

Why C?

ANSI C

**The Embedded
Difference**

Examples

□ **Embedded SW Development**

- 2. Tool/chip selection
- Needs based on **memory size**, **speed** and special feature availability will determine which device will be most appropriate. Issues such as cost and availability should also be investigated.
- It is essential to determine if the development decisions you have made are possible with the device you are considering.
- **Example:** using C => compiler for C
- It is also useful to investigate the availability of emulators, simulators and debuggers
- 3. Software plan
- Select an algorithm which solves the problem specified in your problem specification
- The overall problem should be broken down into smaller problems
- **Example:** The home thermostat project quite naturally breaks down into modules for each device and then each function of that device

The Embedded Difference

Why C?

ANSI C

**The Embedded
Difference**

Examples

□ **Embedded SW Development**

- 4. Device plan – hardware specific routines
 - 1) **Set up the reset vector**
 - 2) **Set up the interrupt vectors**
 - 3) **Watch the stack (hardware or software)**
 - 4) **Interact with peripherals such as timers, serial ports, and A/D converters**
 - 5) **Work with I/O ports**
- 5. Code/debug
 - Syntactic correctness of the code
 - Timing of the program
- 6, 7. Test, Integrate
 - Test each component and integrate in a functional product (project)
